```php
class SubscriberData extends Data
{
    public function __construct(
        public readonly ?int $id,
        public readonly string $email,
        public readonly string $first_name,
        public readonly ?string $last_name,
        /** @var DataCollection<TagData> */
        public readonly null|Lazy|DataCollection $tags,
        public readonly null|Lazy|FormData $form,
    ) {}
}
```

The basics are very similar to a pure PHP DTO, but we have this `Lazy` thing. I will talk about it later, but it's very similar to the `whenLoaded` method used in Laravel resources (it helps us avoid N+1 query problems). So we have a subscriber with a nested `TagData` collection and a nested `FormData` property.

This package can create a DTO from a request automatically. Since it can be used as a request, we can define validation rules:
